RÉCUPÉRATION MOTRICE ET FONCTIONNELLE APRÈS UN AVC: MESURER, C'EST SAVOIR, CAR DEVINER, C'EST SE TROMPER

Geert Verheyden
PhD
Professeur de réhabilitation neurologique,
KU Leuven

L'applicabilité et la pertinence des instruments pour la pratique clinique sont abordées plus en détail sur la base de modèles prédictifs, dans lesquels les informations recueillies au cours des deux premières semaines ou lors de l'admission au centre de rééducation donnent des indications claires quant à la récupération de la fonction du membre supérieur touché et à la capacité/incapacité à marcher ou à exécuter des tâches simples du quotidien de manière autonome 3 ou 6 mois après l'AVC ou à la sortie du centre de rééducation. Bien que les modèles prédictifs ne soient qu'indicatifs et n'aient généralement pas fait l'objet d'une validation croisée dans un nouveau cadre international, cela démontre l'exploitabilité de différents instruments de mesure et la pertinence de leur utilisation à des moments concrets. De cette manière, la rééducation motrice et fonctionnelle peut être adaptée au patient, des indications relatives à la récupération peuvent être données à un stade précoce au patient et à sa famille, et les perspectives d'avenir du patient peuvent être évoquées de manière raisonnable dans le cadre d'une concertation interdisciplinaire.

38

Pronostic capacité de marche

Prognosis for walking ability 6 months after the stroke 16, 17

It has been demonstrated that establishing an estimated prognosis for the patient's walking ability 6 months after the stroke requires their sitting balance (assessed with the sitting balance item of the Trunk Control Test) and the motor function of the leg (assessed with the Motricity Index) to be recorded as soon as possible, but preferably on day 2 after the stroke. (Level 1)

Pronostic capacité de marche

TWIST est plus précis que les kinés pour prédire si un patient sera capable de marcher de manière autonome 4, 6 ou 9 semaines après un AVC, mais pas 16 ou 26 semaines après.

TWIST peut être utile pour orienter la rééducation précoce et planifier la sortie de l'hôpital.

 - Recommandations de bonne pratique
 - Pronostic
 - Rééducation de la marche: principes généraux
 - Rééducation de la marche: méthodes spécifiques
 - Conclusion

55

Guidelines: principes généraux

Intensity of exercise training 5

● It has been demonstrated that increasing the intensity of therapy (in terms of more hours of exercise) for patients with a stroke, compared to less intensive exercising, results in more rapid recovery of *selective movements, comfortable walking speed, maximum walking speed, walking distance, muscle tone, sitting and standing balance, performance of basic activities of daily living, and severity of depression and anxiety.* (Level 1)
 Studied for ER (✓), LR (✓), RC (✓).

Veerbeek and coll. © 2014 Royal Dutch Society for Physical Therapy
 Cliniques universitaires Saint-Luc – Thierry Lejeune

56

Guidelines: principes généraux

Task specificity of training effects

6

It has been demonstrated that training specific skills, such as exercising balance while standing and reaching to grasp objects, has a favorable effect on the specific skill being trained by stroke patients, in all phases of rehabilitation. Transfer to other skills, which were not specifically trained during the therapy, has however hardly been demonstrated. (Level 1)

Veerbeek and coll.

© 2014, Royal Dutch Society for Physical Therapy

Cliniques universitaires Saint-Luc – Thierry Lejeune

57

57

Guidelines: principes généraux

Context specificity of training effects

7

It has been demonstrated that training stroke patients in a functional context has a favorable effect on learning specific movements or skills, regardless of the patient's rehabilitation phase. If possible, patients with a stroke should preferably be rehabilitated in their own domestic and community environment. (Level 1)

Veerbeek and coll.

Robot-assisted gait training 51, 52

It has been demonstrated that robot-assisted gait training for stroke patients who are unable to walk independently improves their *comfortable walking speed, maximum walking speed, walking distance, heart rate, sitting and standing balance, walking ability* and performance of *basic activities of daily living*, compared to conventional therapy (including overground walking). (Level 1)

Circuit class training for walking and other mobility-related functions and activities 59

● It has been demonstrated that circuit class training (CCT) for walking and other mobility-related functions and activities improves walking *distance/speed*, *sitting and standing balance* and *walking ability*, and *reduces inactivity* in patients with a stroke. (Level 1)

Walking distance/speed studied for ER (✓), LR (✓) and RC (✓), sitting and standing balance for ER (✓), LR (✓) and RC (✓), walking ability for ER (✓), LR (✓), and RC (✓), and inactivity for LR (✓) and RC (✓).

Conclusion

Current knowledge

Strong recommendations

Measurement

- ✓ 10MWT
- ✓ 6MWT
- ✓ Functional gait assessment

Intervention

- ✓ Tailored
- ✓ Task-oriented
- ✓ Repetitive practice

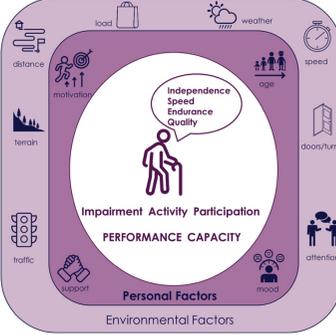

Delivery methods:

- ✓ Circuit Class
- ✓ Treadmill
- ✓ Cardio-respiratory fitness training

Emerging innovations

- Optimising dosage
- Personalized interventions
- Targeted biomechanical factors
- Enhancing motor learning
- Neuro-modulation
- Behaviour change techniques

WALKING RECOVERY MODEL FOR STROKE

Future roadmap

Driven by stroke survivor needs

Increase evidence-base

Measurement:

- Focus on performance measures
- Biomarkers for prediction
- Big data & data-sharing

Intervention:

- Large studies, global team development
- Robust trial design
- Understand:

Why? What? Who? When? Where? How Much? How? Tailoring? How Well?

Implement what we know

- Apply common language
- Recommended measures / interventions
- Invest in people
- Environments & service delivery pathways to promote recovery
- Supported self-management
- Technology
